Cognition is the way we use mental skills to acquire knowledge, manipulate ideas, and process new information and beliefs. The Strategic Thinking Questionnaire (STQ), which measures three such skills – systems thinking – reframing – reflection, was used to collect data from students preparing for school leadership roles at four universities in the United States (USA), Malaysia, Hong Kong, and Shanghai. It was thought that the use of these skills might vary from country to country because of western and eastern cultural norms. Based on self-reported data from 328 educators preparing for school leadership roles we concluded that the use of strategic thinking skills were found in all locations but the variance in their use is more a function of age of respondents, and gender rather than location. These findings have implications for training, professional development, and selection of aspiring leaders.

The ability to interpret and make meaning of discreet and seemingly unrelated events is a

hallmark of today's successful leader. This ability should help leaders think strategically by

understanding, identifying, predicting, responding, and adapting to opportunities and challenges

confronting them. The need for school leaders to think strategically has gone unchallenged as the

world reacts to the effects of globalization, which are creating a profound challenge for all

organizational leaders. In 2006, Pisapia noted that leaders who find themselves in such messy,

chaotic, complex environments fail because they are trained in and rely upon a linear thinking

mindset that does not work in situations characterized by ambiguity and complexity. They are

---

[1] Presented at the **CCEAM 2008 Conference**, 8 - 12 September 2008, ICC Durban, South Africa

unable to identify critical societal and institutional forces influencing their environment and thus

do not connect their organizations to the current major themes associated with success. Their

concept of change is also linear; therefore, they overuse quantifiable parameters in the change

process and seek to rationally plan their way to success. By failing to consider that their

organizations is dependent upon the actions and views of other organizations and individuals; they

do not connect with significant forces on their critical paths of success. Schreyogg and Noss (2000)

and Weick and Quinn (1999) support the claim that there is an over reliance on linearity which

does not fit with today's realities of 'fast and furious' change. This environmental change requires

leaders who can add strategic thinking capabilities to their repertoire of the more common

analytical capabilities long taught in our management schools.

Strategic thinkers work from a mental model of the complete system. This strategic

mindset incorporates an understanding of both the external and internal context of the

organization. Henry Mintzberg (1994) sees strategic thinking as a synthesizing process utilizing

intuition and creativity whose outcome is "an integrated perspective of the enterprise." From this

integrated perspective, strategic thinking challenges existing assumptions and action alternatives,

potentially leading to new and more correct ones.

Strategic thinking is creative, critical, and analytical although accomplishing all types of

thinking simultaneously is difficult, because of the requirement to suspend critical judgment. When

applied correctly, strategic thinking enables the leader to (a) recognize interdependencies,

interrelationships and patterns, and (b) make consequential decisions using both powers of

analysis and intuition. Chilcoat (1995) and Pisapia, Reyes-Guerra and Coukos (2005), for example,

suggest that effective leaders demonstrate more complex mental skills than ineffective leaders.

Leithwood and Steinbach (1992) believe that efforts to improve the effectiveness of education may

be more productive if more consideration was given to improving the quality of thinking and

problem solving abilities of administrative and teachers rather than simply focusing on actions or behaviors.

Cognition is the way thinking occurs. Mental or cognitive skills enable the acquisition of knowledge by manipulating ideas and processing new information and beliefs in our minds. Information, memory, reasoning, application of schemas and biases, making attributions and thinking-through a problem are examples of cognitive skills. Some people take *mental shortcuts*, acting on what we expect to see.

The literature identifies many cognitive skills such as: chunking (Agor, 1988; Newell & Rosenbloom, 1981; Simon, 1957, 1999), cognitive reduction (Simon, 1957), cognitive heuristics (Stanwick, 1996), cognitive maps/schemas (March & Simon, 1958; Simon 1957; Stanwick), mental imagery (Anthony, Bennet, Maddox, & Wheatley, 1993; Stanwick), creativity (Depree, 1989). These shortcuts are useful when making quick decisions such as in single loop learning and problem solving to react to circumstances based on taken for granted values, goals, frameworks. The emphasis is on techniques and making the organization more efficient by detecting and correcting error (Usher & Bryant 1989).

At other times, the outcomes being sought are strategic and the need is to learn to see past the façade or assumptions of an issue to examine the underlying situation to understand the psychology and systemic issues present in the situation. The emphasis is on techniques that make the organization more efficient by detecting and correcting error. These times call for other mental tools such as: mental models and schemas (Riedel, Morath, & McGonigle, 2000; Senge, 1990; Weick, 1995;), critical thinking (Baron, 1994; Cohen, Thompson, Adelman, Bresnick, Shastri, & Riedel, 2000; Halpren, 1996; Riedel et al.), pattern recognition (Cohen et al.; Simon, 1957, 1995), reframing (Bolman & Deal, 1994; Morgan, 1986), reflection (Argyris & Schön, 1978, 1996; Dewey 1933; Schön, 1983), and systems thinking (Senge). One way to do this is to become a master of asking powerful questions.

Considering that, this listing is not exhaustive, some have argued (e.g., Perkins, 1995) there may be too many strategies for leaders to remember, consider, select, and apply. However, regardless of the architecture presumed to underlie human cognition, the fact is that leaders must retrieve, activate, and/or recreate knowledge to influence actions and perceptions of followers. As Pisapia (2006) suggested a strategic agile mindset is indispensible for modern leaders. Looking for a more parsimonious set of skills, Pisapia and Reyes-Guerra built on the earlier work of Argyris, Schön, and Senge's work to identifying components of strategic thinking. They identified three cognitive skills (systems thinking, reframing and reflection) that enable leaders to think strategically and theorized that they were potential distinguishers between successful and less successful leaders. Thus, they are important skills Universities should teach and aspiring leader should learn.

The Strategic Thinking Skills

We begin by defining the three strategic thinking skills that appear to be related to leader success (Pisapia, Reyes-Guerra & Coukos, 2005; Pisapia, Reyes-Guerra & Yasin 2006) These three skills assist leaders in (a) reframing situations so they become clearer and more understandable; (b) reflecting and developing theories of practice which guide actions; and, (c) thinking in more holistic ways. They also aid leaders in seeing events and problems in terms of concepts, which are useful ways of thinking effectively about problems.

Fluency in multiple frames is a basic skill for postmodern leaders. It is critical for them to make their dominant frames explicit and to widen their frame repertoire. Pang and Pisapia (2006) suggest that leaders must frame and place all situations in context. Framing is a cognitive process that helps individuals gather and organize information and create knowledge. It involves sorting and interpreting the meaning of new information, events, and experiences. Framing imposes provides a language for analysis of behavior in which aspects of situations are interpreted through multiple lenses. Typically, individuals reach for frames when trying to understand new,

complicated events and how communications, goals, and initiatives could be perceived. However, the manner in which a leader frames a situation is crucial to his or her understanding and public reasoning.

Reframing is a conscious effort by leaders to switch attention across multiple perspectives in order to generate new insights and options for actions. The goal is to produce usable knowledge by rotating through appropriate conceptual models for the activities and events observed. This process can overcome Bolman and Deal's (1991) assertion that using singular frames filter out some things and allow others things to pass through quickly. "The ability to reframe experiences enriches and broadens a leader's repertoire and serves as a powerful antidote to self entrapment" (pg 4). Reframing a problem involves a conscious effort to size up a situation using multiple lenses. Bolman and Deal (1991: 17) assert that:

> Managers who master the ability to reframe report a liberating sense of choice and power. They are able to develop unique alternatives and novel ideas about what their organization needs. They are able to tune in to people and events around them and less often startled by organizational perversity, and they learn to anticipate the turbulent twists and turns of organizational life. The result is managerial freedom – and more productive, humane organizations.

Reframing in this study refers to leaders' ability to switch attention across multiple perspectives, frames, mental models, and paradigms in order to generate new insights and options for actions. It enables one to sort through problems and opportunities, to see problems in ways that allow them to map out different strategies, and identify trends before others see them. Someone with this ability would be able to recognize when information is presented from only one perspective. They would also demonstrate a willingness to seek different viewpoints on complex problems, ask those around them what they think is changing, and discuss solutions with critics and challengers as well as supporters.

Reflection is a cognitive skill that involves careful consideration of any belief or practice that promotes understanding of situations and then applies the newly gained knowledge to these situations. It relies on subjecting evidence, perceptions, and experience to critical scrutiny, but suspending critical judgment, in order to make sense and meaning of situations prior to weaving the thinking into a theory of practice. By reflecting on both successes and failures, leaders begin to unpack the assumptions and values that lie beneath rules, regulations, and skills in work and everyday life. This constant effort of reevaluation and interpretation is an integral part of how leaders make sense of situations. Even though the leader is without all the information needed, the use of reflection will offer the best possible options for action and prediction. Senge (1990) uses the three types of reflection when he describes professional practice based on reflective thinking in terms of levels. Senge (1990: 2) says,

> The first level is technical reflection, which is concerned with examining the efficiency and the effectiveness of means to achieve certain ends. The second level, practical reflection, involves examining not only the means but also the ends, questioning the assumptions and the actual outcomes. The third level is critical reflection, which considers the moral and ethical issues of the social compassion and justice along with the means and the ends, encompassing the first two levels.

Of the three types, critical reflection is the most necessary for transforming oneself and ones organizations. As Mezirow (1990: 12-13) points out, 'We become critically reflective by challenging the established definition of a problem being addressed, perhaps by finding a new metaphor that reorients problem-solving efforts in a more effective way.'

Argyris and Schön (1978) have a similar way of describing reflective thought. They differentiate between single and double loop learning. They describe single-loop learning as a reaction to circumstances based on taken for granted values, goals, frameworks, and to a significant extent, strategies are taken for granted. They point out that, in single loop learning,

reflection is focused on making the organization more efficient and the detection and correction of error. The emphasis is on techniques and making them more efficient (Usher and Bryant 1989). In single loop learning, the assumptions governing a situation are not questioned. If reflection occurs in this situation, it is simply to make the organization more efficient. They just look for another strategy to achieve its present objectives.

Transformative learning is accomplished through double loop learning which is applied when *coping* will not be sufficient to gain organizational fitness. It is used to change the organization's mindset; its core set of principles, beliefs, and norms. Double loop learning, which is *deeper* than *single loop* learning, emerges when members review new environmental challenges and critique current organizational assumptions and ways of doing business to determine if new responses and new basic assumptions need to be embraced to gain organizational fitness.

Reflection, in this study, refers to leaders' ability to weave logical and rational thinking together with experiential thinking through perceptions, experience, and information to make judgments as to what has happened and then creates intuitive principles that guide future actions. In reflection, one uses perceptions, experience, and information to make judgments as to what has happened in the past and is happening in the present to help guide their future actions. Someone with this ability would be able to understand the past, present, and perhaps the future by recognizing why certain choices worked and others did not. They would demonstrate a willingness to question their assumptions and test whether their behaviors actually result in desired outcomes. It enables one to use perceptions, experiences, and knowledge to understand situations, how to think about them and inform action.

Systems' thinking requires that the leader understands that he or she is part of a feedback process, not standing apart from one. This understanding represents 'a profound shift in awareness' that there is connectivity between members of organizations that influences the way a system works. The perspective gained from looking at feedback in this way 'suggests that everyone

shares responsibility for problems generated by a system' (Senge 1990: 78). This feedback

perspective becomes especially significant when leading organizations. Organizations are always

involved in skills that determine their output and direction. Senge (1990: 87) recommends that in

order to understand a balancing feedback process the systems thinker must 'start at the gap – the

discrepancy between what is desired and what exists… then look at the actions being taken to

correct the gap'. The leader must then translate the understanding into action. Senge (1990: 114)

emphasizes that the 'bottom line of systems thinking is leverage – seeing where actions and

changes in structures can lead to significant, enduring improvements'.

Systems thinking, in this study, refers to leaders' ability to see systems holistically by

understanding the properties, forces, patterns, and interrelationships that shape the behaviors of

the systems which provide options for actions. This definition requires that leaders think

holistically, defining the entire problem by extracting patterns in the information one collects

before breaking the problem into parts. This capability enables someone to understand how facts

relate to each other. It also enables them to seek the cause of a demand for products or services

that their organization produces before taking action to meet the demand and seek feedback to

help individuals and the organization self correct.

Purpose

This paper reports an exploration into the use of foundational thinking skills -

systems thinking, reframing, and reflection –needed for strategic thinking – by educators

preparing for school leadership roles in the USA, Hong Kong, Malaysia, and Shanghai. The

study's purpose was limited to answering the following two questions:

1.   Do students preparing for leadership roles in the USA, Hong Kong, Malaysia, and Shanghai

use strategic thinking skills differently?

2.   How do contextual variables of location, age, and gender affect the use of strategic

thinking skills?

METHODS

The examination of the cognitive aspects of leadership development has largely gone

unnoticed in the research on leadership. Thus, creating a vacuum in an area of leadership

identification and development that has both been recognized over 70 years ago in seminal works

regarding reflection (Dewey, 1933, Argyris & Schön, 1978) and brought to the forefront over 10

years ago concerning reframing (Morgan, 1986; Bolman & Deal, 1991) and during the last 35 years

concerning systems thinking (Bertalanffy, 1968; Senge, 1990). Hence, we conceived of this data

collection as non-experimental and exploratory since modest research has been conducted on

these variables.

Sample

For this study, a purposeful sample of 328 English-speaking students preparing for school

leadership positions at The Chinese University of Hong Kong, University of Malaya, China Executive

Leadership Academy, and Florida Atlantic University was drawn for analysis. The University of

Malaya provided two subsamples; one from Kuala Lumpur (n=52) and the other from Sarawak on

the island of Borneo (n=59). Table 1 presents the demographic data for the participants in the

study by site.

Table 1
The Demographics of Participants in this Study

			Location								
	Sample		**USA**		**HK**		**KL**		**Shanghai**		**Borneo**	
Gender	N	%*	N	%*	N	%*	N	%*	N	%*	N	%*
Male	135	41	9	14	49	48	28	54	6	12	43	73
Female	193	59	55	86	53	52	24	46	45	88	16	27
AGE												
20-25	76	23	25	39	0	0	0	0	51	100	0	0
26-34	61	18.6	23	36	26	26	0	0	0	0	12	20
35-44	138	42.1	14	22	47	46	47	90	0	0	30	59
45-54	53	16.2	2	3	29	28	5	10	0	0	17	29
N	328	100	64	20	102	31	52	16	51	16	59	18

  ∗   = percentages may not add to 100 due to rounding of numbers.

As seen in Table 1, Hong Kong (HK) provided 31% of the sample. All other sites produced

from 16 to 20% of the sample. Females composed 59% of the total sample. Their prevalence was

apparent in the USA and Shanghai samples. Males were more prevalent in the Borneo sample.

The Shanghai students were the youngest and still in the process of acquiring their

bachelors degree in education. The USA sample was younger than the HK and Malaysian samples.

Eighty four percent of the USA sample fell into the 20-44 age groupings. Ninety eight percent of the

HK and Borneo samples fell in the 35- 54-age groupings. One hundred percent of the Kuala Lumpur

(KL) sample fell in the same age categories.

Instrumentation

The STQ*©* v4 was used to collect the data for this study. Version4 is six pages long and

consists of forty-eight Likert type questions. The STQ provides an assessment of three skills –

systems thinking, reflection - reframing - thought to be important to useful in self-assessment and

for development in classes and/or seminars. The STQ*©* asks respondents how often they use the

skills when confronted with problems. It is only available in a self-format since it is felt that only

the test taker can describe how often they employ the skills. Typically, participants return the

instrument directly to the researchers or seminar facilitator. The STQ takes approximately fifteen

or twenty minutes to complete and is capable of being either self or computer scored.

Development. The original STQ*©* developers (Pisapia, Reyes-Guerra, & Coukos (2005)

reviewed the literature and then defined the three cognitive skills. Using the definitions as guides,

they wrote statements describing skills required to think in systems, reframing, and reflection

terms. A panel of five experts knowledgeable about strategic thinking reviewed the resulting 180

items. They sorted the statements into the three categories. In an iterative fashion, the statements

were modified or discarded following lengthy discussions and repeated feedback sessions between

the panel and researchers. Items on the STQ are cast on a five-point Likert scale. A higher value

represents greater use of a cognitive skill, as noted below:

1= Almost Never uses

2 = Rarely uses

3 = Sometimes uses

4 = Frequently uses

5= Almost Always uses

Reliabilities. Following each administration (4 now) of the STQ, the items were subject to

empirical analyses followed by discussions conducted in an iterative fashion until the statements

were representative of the strategic thinking construct. Ongoing analysis and refinements in the

instrument continue, with a database involving approaching 3,000 respondents. Table 2 presents

the means, standard deviations and Cronbach Alpha's for the STQ Version3 and Version4.

Table 2.
Means, Standard Deviations and Reliability Coefficients of the Subscales of the Strategic
Leadership Questionnaire: Version3, 2007 and Version4, 2008.

Dimension	Version3					Version4				
	M	**SD**	**N**	**Alpha**	**#items**	**M**	**SD**	**N**	**Alpha**	**#Items**
Systems Thinking	3.55	.318	643	.713	12	3.67	.486	330	.870	17
Reframing	3.45	.286	643	.777	12	3.43	.433	330	.818	17
Reflecting	3.48	.281	643	.752	12	3.66	.416	330	.742	14
Strategic Thinking	3.50	.247	643	.891	36	3.59	.411	330	.928	48

In STQv3, the rank order of skill usage is systems thinking (3.55), reframing (3.45), and

reflecting (3.48). Based on the mean scores, it was expected that systems thinking would be the

skill most frequently used, followed by reframing. Internal reliabilities of Version3 were assessed

through the standardized Cronbach's alpha. A .70 value generally considered to indicate a

sufficient reliability by classical psychometric authorities (Nunnally, 1978; Peterson, 1994).

Reliability statistics for the STQv3 (based on approximately 643- ratings by a multi-sector sample of

managers in business and education) where computed. Internal reliabilities ranged between .71

and .77 for the subscales and .89 for the total scale. Other studies have found similar reliabilities.

For instance, Pisapia, Reyes-Guerra & Coukos (2005) reported reliabilities ranging from .77-.83 on

subscales and .91 for the scale.

As seen on Table 2, internal reliabilities (Cronbach alphas) on the STQv4 are higher than

Version3 on all scales except reflecting. This may be explained by in difference in number of items

on the scale from v3 to v4. They range between .74 and .87 for the subscales and .93 for the scale

meeting the .70 standard. Additionally, the rank order of the means on the subscales reveal that

the systems thinking is the cognitive skill most frequently used as expected from the version3 and

earlier administrations. However, the reflecting skills (3.66) surpassed reframing (3.43) as the

second most used skill. Thus, the rank ordering of means among the v4 sub scales is exactly the

same v3 subscales except that they were used more often by this sample.

Factor Structure. The STQ was originally developed from an interpretation of the literature

on strategic thinking as being composed of systems thinking, reframing and reflection. The

literature portrayed reframing as part of reflection. The researchers believed that reframing was an

important skill in its own right. Hence, it was originally extracted and tested as a unique variable

from reflection in order to give it emphasis. The skills embodied in systems thinking, reframing and

reflection reveal the participants ability to think flexibly, conceptually and strategically. The

interpretation of these dimensions provides participants with a deeper understanding of their own

mental processing skills. However, in daily use, the three cognitive skills overlap considerably; but

best taught singularly. Theoretically, the STQ©v4 measured the participant's capability to think

strategically. It included 17 items from systems thinking, 14 from reframing, and 14 reflection

items. The STQv3 when subjected to factor analyses produced one predictive factor – the overall

strategic thinking score (Pisapia, Reyes-Guerra, & Yasin 2006).

Version4 was subjected to a principle axis factoring method with iterative communality estimation and oblimin with Kaiser Normalization rotation. The two factors (systems thinking and reflection) with Eigenvalues greater than 1.0 reported in Table 3 accounted for 52 percent of the variance. Values less than the .10 threshold were suppressed and not reported on the table. One might argue that the difference may not be in level or variance on the factors derived with the complete data set, rather, that the factors themselves are different across cultural groups. With these data, the point may be a good one, but not enough subjects were available to consider cross-cultural factor agreement though separate factor analyses.

Table 3.
Factor Structure (Factor Loadings) for the STQv4. (n=328)

Item #	Factors		Item
	Systems Thinking	**Reflecting**	**Stem:** **When facing difficult problems, How often do you:**
4	**.738**	.169	Ask those around you what they think is changing?
6	**.594**		Try to find a common goal when two or more parties are in conflict?
44	**.544**	-.167	Think about how different parts of the organization influence the way things are done?
24	**.523**		Try to identify external environmental forces which affect your work?
13	**.429**	-.138	Engage in discussions with those who hold a different world view?
47	**.397**	-.131	Define the entire problem before breaking it down into parts?
17	**.370**	-.242	Consider the results of past actions in similar situations?
3	**.321**	-.183	Try to extract patterns in the information available?
31		**-.792**	Frame the problems you face in ways that allow you to understand them?
29		**-.667**	Look at actions being taken to correct the discrepancy between what is desired and what exists?
20		**-.642**	Ask "WHY" questions to develop an understanding of problems?
33	.206	**-.558**	Use different points of view to map out different strategies?
26	.170	**-.525**	Try to understand how the people in the situation are connected to each other?
32	.244	**-.501**	Look for fundamental long-term corrective measures?

Extraction Method: Principal Axis Factoring. Rotation Method: Oblimin with Kaiser Normalization. Rotation converged in 17 iterations. Values less than the .10 threshold were suppressed

By factoring the 48 questions on the STQ©v4, two interpretable factors that are consistent with the definitions of systems thinking and reflection were obtained. This result is inconsistent with the hypothesized three subscales of the STQ but consistent with the literature on the subject. The two factors (Systems Thinking and Reflection) will be the guiding framework for continued research and teaching of strategic thinking skills until empirical analyses confirms the reframing subscale.

Data Collection

The STQv4 was administered in different ways in each of the locations. The USA English version4 was used in the USA and Borneo data collections. In KL and Shanghai, the English version was translated into Malay and Mandarin. Local researchers translated the STQ and then a colleague retranslated it back to English. They shared their English translations with the USA developers and through an iterative process; the translated versions came closer to the USA version4. In Hong Kong, the local researcher presented the English version4 in hard copy but answered questions from students concerning the meaning of certain English words.

<div align="center">

RESULTS AND DISCUSSION

</div>

Two research questions guided the data collection and analyses.

> *Research Question 1*: Do students preparing for leadership roles in the USA, Hong Kong, Malaysia, and Shanghai use strategic thinking skills differently?
>
> Research Question 2: Do contextual variables of age, gender affect the use of strategic thinking skills?

The data are displayed and analyzed with descriptive statistics and multiple univariate analyses of variance. An alpha level of 0.05 was set for all statistical tests. Eta ^{2} was used to investigate effect sizes.

Use of Strategic Thinking Skills

The use of strategic thinking skills among students preparing for leadership roles in the roles was investigated by comparing the means for participants at each location. As seen on Table 4, the rank order use of strategic thinking skills is Borneo, USA, Kuala Lumpur, Hong Kong, and Shanghai.

Table 4

Comparison of Means by Location

Location	Reflection					Systems Thinking				
	M	SD	MN	MX	N	M	SD	MN	MX	N
USA	3.85	.584	2.50	4.83	64	3.85	.463	2.75	4.75	64
HK	3.70	.507	2.33	4.83	102	3.53	.467	1.75	4.75	102
KL	3.78	.540	1.17	4.83	52	3.66	.504	1.50	4.63	52
Shanghai	3.09	.488	1.83	4.00	51	3.01	.406	2.13	3.88	51
Borneo	4.00	648	1.93	5.00	59	3.90	.500	2.25	4.75	59
Total	3.70	.616	1.17	5.00	328	3.60	.551	1.50	4.75	328

The two highest scoring locations (Borneo and USA) both administered the English Version4 of the STQ. Participants at these locations were dissimilar on age and gender variables. Borneo participants were overrepresented by males (73%) and the USA participants were overrepresented by females (86%). While males in Borneo and females in the USA represent a greater proportion of those preparing for leadership roles, both groups were overrepresented in each sample. The USA sample was younger than the Borneo sample. Eighty four percent of the USA sample fell into the 20-44 age groupings. Ninety eight percent of the Borneo samples fell in the 35-54-age groupings.

In KL, the STQ was translated and administered in Malay. The results were consistently at the middle of the rank order of means. There was a more even distribution of males (54%) and females (46%) than in the USA and Borneo locations. On the age variable, ninety percent of respondents were in the 45-54 age group compared to the sample mean of forty two percent.

In Shanghai, the STQ was translated into Mandarin and the match with the English version achieved high fidelity. However, the results from this location were consistently low in comparison to the other locations.

Table 5 presents the relationship between location and strategic thinking and reflection. The means for the criterion variables found in Table 5 were obtained by summing the items comprising the empirical factor for each of the two scales. As can be seen on the table the

relationship between locations (country) and the two criterion variables were significant and the

effect sizes were .03 for systems thinking and .037 for reflecting indicating a small effect.

Table 5
Test between location and systems thinking and reflecting.

Source	Criterion Variable	Type III Sum of Squares	df	Mean Square	F	p	Partial Eta Squared	Noncent. Parameter	Observed Power(a)
Location	Systems Thinking	2.035	3	.678	3.155	.025	.030	9.466	.729
Location	Reflecting	3.434	3	1.145	3.844	.010	.037	11.532	.819

a Computed using alpha = .05

A pairwise comparison of the means between location and the criterion variables was

conducted to understand the significant finding. As seen on Table 6, the Shanghai sample used

both reflection and systems thinking skills significantly lower than other locations in the sample.

The major distinguishing characteristics of the Shanghai respondents were age and gender. Eighty

eight percent were female, and one hundred percent of them fell in the 20-25 age category.

Table 6
Comparison of Means for Location and Reflection and Systems Thinking Skill.

Based on estimated marginal means
1 = mean difference
*The mean difference is significant at the .05 level.
a. Adjustment for multiple comparisons: Bonferroni

Also noted on Table 6, there were no significant differences between Borneo, KL, and the USA on either scale. However, the USA and Borneo usage of reflection and systems thinking skills usage was significantly greater than Shanghai and HK. The USA and Borneo respondents used systems thinking significantly greater than Shanghai and HK.

Besides a significant difference with Shanghai on both scales, HK produced significantly,

lower usage rates compared to Borneo on reflection and Borneo and the USA on the systems

thinking scale.

The data from the respondents in two Asian cities differed from the data presented by the

respondents in the two Malaysian cities as well as the United States. These significant differences

could represent a cultural difference, differences in administration of the STQ, sample size and

characteristic differences. To explore an explanation an examination of the influence of age and

gender individually and combined on the results for each location.

The Effect of Contextual Variables

The second research question asked if age and gender affect the use of strategic thinking

skills. The results on these variables were examined individually, and then their interactions were

explored.

Gender. The possible impact of gender on systems thinking and reflection usage scores was

analyzed by comparing the differences between male and female respondents. Women totaled

fifty-nine percent of the sample. (N=193 versus N=135). The univariate analysis of variance

displayed on Table 7 indicates that there were no significant differences in the means of systems

thinking and reflecting attributed to gender.

Table 7
Test between Gender, Systems Thinking and Reflecting.

Source	Criterion Variable	Type III Sum of Squares	df	Mean Square	F	p	Partial Eta Squared	Noncent. Parameter	Observed Power(a)
Gender	Systems Thinking	.669	1	.669	3.114	.079	.010	3.114	.421
Gender	Reflecting	.276	1	.276	.926	.337	.003	.926	.276

a Computed using alpha = .05

As a comparison of the female and male means on Table 8 indicate that although males reported higher mean scores on reflection and systems thinking usage, there were no significant differences found between the two groups. Thus, the STQv[4] seems to be free of gender bias.

Table 8
Comparison of Means for Gender, Reflection, and Systems Thinking Skills

Gender	Reflection						Systems Thinking					
	Gender	M	SD	MD[1]	SE	p	Gender	M	SD	MD	SE	p
Male		3.77	.609					3.64	.564			
	Female			.133	.069	.053	Female			.075	.062	.227
Female		3.64	.615					3.57	.541			
	Male			-.133	.069	.053	Male			-.075	.062	.227

[1] = Mean Difference
Based on estimated marginal means

Age. The possible impact of age on strategic thinking skills was tested by comparing the differences among the five age categories – 20-25, 26-34, 35-44, and 45-54. A univariate analysis of variance was conducted. As can be seen on the Table 9, the relationship between age and the two criterion variables were significant and the effect sizes were .151 for systems thinking and .109 for reflecting indicating a moderate effect.

Table 9
Test between Age, Systems Thinking and Reflecting.

Source	Criterion Variable	Type III Sum of Squares	df	Mean Square	F	p	Partial Eta Squared	Noncent. Parameter	Observed Power(a)
Age	Systems Thinking	11.666	4	2.916	13.570	.000	.151	54.278	1.000
Age	Reflecting	11.131	4	2.783	9.345	.000	.109	37.378	11.131

a Computed using alpha = .05

A comparison of the means between location and the criterion variables was conducted to understand the finding. As seen on Table 10, the age group 20-25 used both reflection and systems thinking skills significantly less than other age categories in the sample. No other significant

differences were present in the data. Furthermore, both reflection and systems thinking means

rise as age rises.

Table 10

Comparison of Means for Age, Reflection, and Systems Thinking Skills

Age	Reflection						Systems Thinking					
	AGE	M	SD	MD[1]	SE	P[a]	AGE	M	SD	MD	SE	P[a]

[1] = Mean Difference
Based on estimated marginal means
a Adjustment for multiple comparisons: Bonferroni.

The lowest use of strategic thinking skills was reported significantly less by respondents in the age category 20-25. Reflection (M=3.34) and systems thinking (M=3.25) rose incrementally from age category 20-25 to age category 45-54 for reflection (M-3.99) and systems thinking (M=3.84).

In this study, two samples presented respondents in the 20-25 age category. The 51 Shanghai respondents (100% of sample) fell into the 20-25 age category. They reported using reflection (M=3.08; SD .488), and systems thinking (M=3.01; SD=.406) skills. The USA, on the other hand, presented thirty-nine percent (39%) of its 64 respondents in the 20-25 age category. These respondents reported using reflection (M=3.86; SD=.517) and systems thinking (M= 3.75; SD= .487). No other site presented respondents in the 20-25 category.

Moderation Effects. The interactions among location, age, and gender were then explored to determine their effects on usage of systems thinking and reflecting. The interaction of location, gender, age and systems thinking and reflecting produced no significant effects. (See Table 11)

Table 11
Moderation effects between Age (A), Gender (G) and Location (L) in regard to Systems Thinking and Reflecting

Source	Criterion Variable	Type III Sum of Squares	df	Mean Square	F	p	Partial Eta Squared	Noncent. Parameter	Observed Power(a)
L*G	Systems Thinking	.522	3	.174	.809	.490	.008	2.427	.224
L*G	Reflecting	1.186	3	.395	1.328	.265	.013	3.984	1.186
L*A	Systems Thinking	.542	5	.108	.504	.773	.008	2.520	.187
L*A	Reflecting	2.329	5	.466	1.565	.170	.025	7.823	.545
G*A	Systems Thinking	.633	4	.158	.737	.567	.010	2.947	.237

a Computed using alpha = .05

Summary of Findings. These analyses indicate that:

1.   Location explains approximately 4% of the variance in reflection and 3% of the variance in systems thinking. Examination of the means for each location indicates that Borneo used systems thinking and reflecting skills significantly more than Shanghai and HK. The USA used systems thinking skills significantly more than Shanghai and reflecting significantly more than HK and Shanghai. HK used system thinking significantly more than Shanghai. KL used systems thinking and reflection significantly more than Shanghai. Shanghai used systems thinking and reflecting skills significantly less than all other locations.

2.   Gender produced no significant effects with the use of systems thinking and reflecting skills.

3.   Age explains approximately 11% of the variance in reflection and 15% of the variance in systems thinking. Respondents in the age category 20-25 reported using systems thinking and reflecting skills significantly less than all other age categories. No other age category produced significant inter-category effects. The means for both the use of systems thinking and reflecting skills rose from a low use for category 20-25 to higher use for age category 45-54

4.   The combinations of location, age and gender produced no significant interactions.

Conclusions and Implications

There are three conclusions drawn from the study.

1.   The improvements in the STQ Version4 have been noteworthy. The reliabilities are stronger than earlier versions. The two subscales (systems thinking and reflection) enable the instrument to be used for predictive studies, and provides a sound factor foundation to continue to validate the reflection subscale. On the results side, we were able to generate firmer confidence in the results found earlier studies.

2.   This is the first study that directly compared the use of strategic thinking skills as measured by the STQ across different locations. As seen in the previous paragraphs, there were some differences across the different locations. The Borneo and USA samples used the strategic thinking skills to a greater degree than HK and Shanghai but similarly to the KL site. These differences raised several questions that should be addressed in future studies. Were the differences due to the composition of the sample such as Shanghai and the USA? The way the STQ was administered? The Chinese culture compared to the Malay and USA cultures?

       Our interpretation is that the sample design did not allow comparisons of like samples. Therefore the results seem to be attributed to survey administration and sample make-up not cultural issues.

3.   These data present a potential age bias. Reflection and systems thinking skill usage rises incrementally for each location, as one gets older. (This finding does not apply to Shanghai, which

presented all of its 51 respondents into the 20-25 age category and thus could not be analyzed).

Rather than an age bias, this 20-25 age category could be a proxy for experience and/or education, which are likely moderators of thinking skills. It appears that as age raises so does the use of reflection and systems thinking. This finding has implications for the teaching of these skills in entry college programs as well as throughout the early career years. We recommend a significant effort be made by Universities to emphasize strategic thinking as part of their curriculum for students preparing for school leadership positions.

4. We believe that the results will be useful for the development and identification of executive talent. From an organizational point of view, the STQ© can provide another tool to use in considering who is selected and placed on the career fast track. From the participant point of view, it provides him/her with the necessary feedback for continuous development on an important and hereto untouched set of skills.
